AcquireDynamics Release Notes 1.0.1

1. Offline order entry & hold to sync orders
   a. If you do not have cell service/wifi you can log in via offline mode. From here all orders become 'Pending orders'. These orders support full CRUD operations and can later be 'Published' to D365 one at a time or in a full push.
   b. When doing a full push you get redirected to a 'Published orders' screen that has error handling built in to show the breakdown of created orders, partially created orders, and failed orders.
2. Caching reference data
   a. Users now have the option to pull down reference data from their D365 instance. If they choose to do this the customer and item data will be searchable both by name and number when creating orders and lines.
   b. Users have the ability to manually refresh or clear reference data from the 'User Information' page of the application.
3. Order entry flow change
   a. Orders now begin by selecting a customer, with the support of the reference data feature we can search and select via drop down.
   b. Once a customer is selected the user can determine to create a new order in real time or a 'Pending order' that can be published later.
   c. From here a user will see a new grid view where they have a few choices. They can start manually making a new order from scratch or they can choose to 'Replace last order' which will pull the most recent order for that customer and populate all of the line information. From here the order can be updated as desired.
4. General updates
   a. Refactoring for readability and scalability.
   b. Updating authentication system to remember logged in users until they choose to log out or their auth expires to reduce friction on opening/closing application.
   c. Adding additional error handling, batching, throttling checks, etc.
